Introduction
Crosslinkers and labeling reagents that contain aryl azide or diazirine functional groups are capable reacting to form covalent bonds with other molecules when activated by ultraviolet light. The nonspecific and activatable properties of this class of reagents makes them particularly useful for many research applications including the study of protein:protein interactions, isolating cell surface proteins and preparing labeled probes. Several specific forms of aryl azide compounds exist (Figure 1) that function by the same general reaction mechanism but differ slightly in stability, efficiency and absorbance maximum. The diazirine group is smaller photo-reactive functional group that has been recently developed for use in crosslinker compounds, including activated amino acids. Psoralen is a photoactivatable group that conjugates to nucleic acids.

![Forms of aryl azide and other reactive groups used in photoreactive crosslinking reagents.](image)

When an aryl azide is exposed to UV-light, it forms a nitrene group that can initiate addition reactions with double bonds, insertion into C-H and N-H sites, or subsequent ring expansion to react as a nucleophile with primary amines (Figure 2). The latter reaction path dominates when primary amines are present in the sample. Details of the diazirine reaction are less well known. Photoactivation occurs with long wave UV light (330-370 nm), creating reactive carbene intermediates that form covalent bonds through addition reactions with \( N_2 \) as a byproduct.
Conditions for Photoactivation

A question that often arises with respect to aryl azide linkers is what wavelength and intensity of light is optimal for photoactivation and efficient crosslinking. Pierce researchers have performed only a limited number of experiments to explore these conditions. However, one set of data was generated for the homobifunctional hydroxyphenyl azide crosslinker BASED (Product No. 21564). Experiments with three different lamp sources and several exposure times indicated that activation with long wavelength UV-light (366 nm) for 30 minutes yields the most efficient (complete) crosslinking of the target molecule (in this case, a peptide) and depletion of free crosslinker (Table 1). These data for BASED are probably representative for all the aryl azide reagents, although short wavelength may be better than long wavelength for plain phenyl azides (no hydroxy or nitro group on the phenyl ring). Examination of Table 1 and perusal of the literature (Table 2) indicate that successful photoactivation with these reagents is possible across a wide range of wavelength and time of exposure.

In addition to choosing an appropriate lamp source for photoactivation, consider the following points when preparing conjugation reactions with aryl azide crosslinkers:

- When microcentrifuge tubes are used for the sample, it is most effective to open the cap so that the sample may be exposed directly rather than through the polypropylene sidewall, which shields most of the UV-light. Quartz spectrophotometric cuvettes are an ideal choice for reaction vessels because they allow for optimal exposure of the sample to the UV-light source.

- Samples will become warm or even hot if exposed to intense UV-light for several minutes. Place the sample vial on ice or use some other method to keep the sample cool during UV-light activation.

- Avoid thiol-containing reducing agents (e.g., DTT or 2-mercaptoethanol) in the sample solution during all steps before and during photoactivation. These reagents will reduce the azide functional group to an amine, preventing photoactivation.

- Avoid buffers that contain primary amines (e.g., Tris or glycine) during photoactivation because these will quench the desired reaction. Reaction of the photoactivated aryl azide groups to primary amines dominates if they are present.
Table 1. Lamp conditions and crosslinking efficiency using BASED (Product No. 21564). Identical reactions with BASED and peptide were prepared and photoactivated by exposure at different wavelengths and lengths of time. Conjugation efficiency was determined by HPLC measurement of the percent peptide and crosslinker depleted relative to the starting material (greater depletion corresponds to more complete crosslinking).

Table 2. Lamp sources and conditions used for photoactivation of aryl azide crosslinkers. The information in this table was compiled from older literature references (pre-2000) and is provided only to exemplify the types of conditions used by researchers. For best results, use a high-quality, multifunctional UV lamp, such as our 3UV Lamp, Product No. 95034 (115V) or 95035 (230 V).
