

Rapid Analysis of Pesticides in Difficult Matrices Using GC/MS/MS

Michael T. Hetmanski, Food and Environmental Research Agency, York, UK

Richard Fussell, Food and Environmental Research Agency, York, UK

Michal Godula, Thermo Fisher Scientific, Praha, Czech Republic

Hans-Joachim Hübschmann, Thermo Fisher Scientific, Bremen, Germany

Introduction

Pesticides are widely used in agriculture to protect crops and to improve efficiency of production. Consequently, governments, food producers and food retailers have a duty to ensure that any residues occurring in foods for human consumption are at or below Statutory Maximum Residue Levels (MRLs). Regulation EC 396/2005 adopted in the European Union sets MRLs for more than 500 different pesticides in over 300 different food commodities.¹ Many of these MRLs are set at a default value of 0.01 mg/kg, the typical limit of determination of routine analytical methods. Thus, there is a requirement for residue laboratories to test a wide array of foods for a large number of pesticides at concentrations at or below 0.01 mg/kg, with low costs and fast turnaround times (often < 48 hours). This is most often achieved using multi-residue methods based on the use of a combination of LC/MS/MS and GC/MS techniques to determine pesticide residues in a single generic solvent extract of the sample. One such example is the QuEChERS (Quick, Easy, Cheap, Effective, Rugged and Safe) procedure, which is based on acetonitrile extraction and dispersive solid phase extraction.² Since acetonitrile is readily compatible with LC/MS/MS and allows analysis of several hundred pesticides this approach has gained in popularity. Many of the less polar semi-volatile pesticides not amenable to LC/MS can be analysed using GC/MS. Unfortunately the analysis of acetonitrile by GC/MS is more problematic. The main issues are:

- Degradation of the GC-column phase by the polar solvent
- Poor focusing of chromatographic peaks due to the high polarity and hence the inability to create a well defined starting zone on less polar column films
- Vapor overload of the insert liner with expansion of the sample beyond insert liner dimensions due to the high thermal expansion coefficient
- Contamination of the system by co-extractives which are not removed by the simple dispersive solid phase extraction clean-up employed in QuEChERS.
- Low crop concentration in the final extracts employed by QuEChERS requiring concentration of the extracts.

Because of the above problems, the detection limits for some pesticides can be too high for analysis at the MRL. It is a common practice to overcome these difficulties by concentration of the extract by evaporation, exchanging acetonitrile to a more appropriate GC solvent, or by using large volume injection techniques. However there is the potential to lose volatile analytes (e.g. dichlorvos) during evaporation and solvent exchange. Also the use of large volume injections can lead to more rapid contamination of the injection inlet as well as degradation of the analytical column.

An alternative approach is to make use of the high sensitivity and selectivity of the Thermo Scientific TSQ Quantum XLS GC-MS/MS instrument which can achieve the 0.01 mg/kg target reporting limits even with relatively low volume injections. This also overcomes the problems associated with the thermal expansion of acetonitrile and reduces the amount of matrix injected.

This application note describes the analytical methodology for a fast multi-residue pesticide determination in a difficult matrix (fruit jam), using the QuEChERS extraction/clean-up procedure in combination with the TSQ Quantum XLS™ GC-MS/MS system as the detection system.

Experimental Conditions/Methods

Sample Preparation

The strawberry jam samples were extracted using the citrate-buffered QuEChERS procedure.³ Homogenized sample (10 g) was mixed with water (10 mL) and acetonitrile (10 mL). After the addition of Internal Standard (triphenylphosphate, TPP) the mixture was shaken for 1 minute. Then MgSO₄ (4 g), NaCl (1 g), disodium hydrogen citrate (0.5 g) and trisodium citrate (1 g) were added and the mixture shaken for 1 minute and then centrifuged for 5 minutes at 3000 U/min. An aliquot of the acetonitrile portion (2 mL) was transferred to a new tube and MgSO₄ (300 mg) and primary-secondary amine (PSA) sorbent (50 mg) added. The mixture was shaken (1 minute) and centrifuged for 5 minutes at 3000 U/min. An aliquot of the supernatant (1 mL) was immediately transferred into a GC vial and acidified (10 µL of 5 % formic acid in acetonitrile). Then 1.0 µL of extract was injected into the GC-MS/MS system. The final concentration of sample was 1 g/mL of extract.

Instrument Setup and Conditions

Determination of pesticides was carried out using a TSQ Quantum XLS GC-MS/MS system, equipped with a split/splitless injector and TriPlus automatic liquid sampler (Thermo Fisher Scientific, Austin, USA). The analytical column used was a TR-Pesticide, 30 m x 0.25 mm i.d., 0.25 µm film thickness (Thermo Fisher Scientific, Runcorn, UK).

The GC-MS/MS conditions used are shown in Table 1, the list of selected reaction monitoring transitions applied is summarized in Table 2.

Results and Discussion

In this application note we present a simple and rapid method based on QuEChERS extraction and GC-tandem quadrupole mass spectrometry (GC/MS/MS) determination of 96 priority pesticides plus transformation products in jam samples. The samples of fruit jam were extracted with acetonitrile followed by dispersive SPE clean-up with PSA prior to detection by GC/MS/MS. The high sensitivity and selectivity of the TSQ Quantum XLS GC-MS/MS system has enabled direct splitless analysis using low volume (1.0 µL) aliquots of acetonitrile extracts. This has significantly simplified the sample preparation procedure, while meeting method performance criteria specified by EU method validation and quality control procedures for pesticide residues in food and feed.⁴ To overcome matrix effects, calibration of the GC-MS/MS system was performed using matrix-matched standard calibration solutions.^{5,6}

Validation of the methodology was carried out using samples spiked with known amounts of selected pesticides at concentrations between 0.01 and 0.05 mg/kg for 89 analytes. A further 7 analytes were spiked at higher levels (see Table 3), as reporting limits for these pesticides are correspondingly higher in UK monitoring. The recovery and precision data are summarized in Table 3. Except for chlorothalonil all of the pesticides met the EU DG SANCO method validation criteria.⁴ Pesticides such as captan, dichlofluanid and iprodione, which are frequently difficult to analyse, showed good recovery and precision data. The study on the

improvement of chlorothalonil recovery from the matrix is now under further investigation.

The calibration curves were linear over wide concentration ranges with correlation coefficients (r^2) > 0.98 for all analytes, except for dicofol. Also, the SRM chromatograms demonstrated high selectivity with no significant interferences observed and an excellent signal/noise ratio (> 5:1) for all analytes, even at the lowest calibrated level (5 ng/ml equivalent to 0.005 mg/kg). All analytes, except folpet and diphenylamine, could be confirmed with the second transition in the low level spiked samples. Examples of extracted ion chromatograms for dichlofluanid and deltamethrin at 0.01 mg/kg and captan at 0.02 mg/kg are illustrated in Figure 1. In all cases the detection limits comply with required MRLs.

Conclusion

The QuEChERS-GC/MS/MS multi-residue method described here is a simple, rapid and accurate approach suitable for the monitoring of GC amenable pesticides in accordance with EU requirements. Another advantage of the extraction method used is its applicability to pesticides amenable to LC analysis. During method validation it was found that recovery, % CV and linearity data were within EU DG SANCO criteria for all 96 pesticides, except chlorothalonil at 0.01 mg/kg and dicofol. However the recovery data for chlorothalonil spiked at 0.01 mg/kg (mean 63%, 11 % CV) and the consistent recovery and precision data obtained for dicofol showed that the methodology was suitable for screening purposes.

Extracted ion chromatograms of SRM traces of analytes demonstrated excellent selectivity with no interferences observed and excellent signal/noise ratios (> 5:1), for all analytes at the lowest calibrated level (typically 0.005 mg/kg).

The robustness of the system was further demonstrated during validation and analysis of pork ham samples for the UK Monitoring Programme, when similarly good quality analytical data was obtained for these analytes.
