ABSTRACT

Correct identification of heterogeneity of monoclonal antibodies (mAbs) and antibody-drug-conjugates (ADCs) is an essential analytical tool in the biopharmaceutical industry. High resolution accurate mass spectrometry (HRAM) has established itself as a powerful tool for the characterization of such compounds; however some proteoforms might not be observed due to potential sample complexity. Here, we used the ZipChip[™] system from 908 Devices made of microfabricated glass chips, coupled to a Thermo Scientific[™] Q Exactive[™] Plus or Q Exactive[™] HF mass spectrometer with the Biopharma option to separate and characterize charge variants of the NIST mAb standard and an ADC derived from it. We were able to identify the three published charge variants with 0, 1 or 2 lysine residues. Using the Thermo Scientific™ BioPharma Finder[™] 2.0 software package, accurate intact mass for at least 15 glyco-forms were obtained. The NIST mAb has only one glycan site per heavy chain, which was modified using click chemistry to generate an ADC. The resulting model ADC also had charge variants, which were successfully separated and annotated with the correct MS1 by CEMS.

INTRODUCTION

The main goal of this work was to develop a method to characterize heterogeneous mAb and ADCs in a top-down approach. This was achieved by combining the powerful combination of efficient separation by capillary electrophoresis (CE) and HRAM together with data analysis software. The separation of proteoform charge variants is quite a challenge using chromatography, but CE provides an ideal separation technique for this problem. Microfluidic CE is advantageous for the mAb analysis given its good separation efficiency and short migration times because of high field strength and short separation channel length. The OrbitrapTM mass spectrometer family is also a good option for this application, and the Q Exactive HF MS with Biopharma option, with its extended m/z 8000 range, is particularly well-suited to the analysis of very large biomolecules. The BioPharma Finder software package is specifically designed to characterize complex proteins using dedicated deconvolution of mass spectra for individual time windows in combination with a thorough comparison to a reference database with all variants. In this study, the combination of microfluidic CE separation, MS detection, and data analysis is presented to solve one of the most challenging workflows in the biopharma industry.

MATERIALS AND METHODS

The NIST reference material (NIST mAb standard RM 8671) used in this study has a published sequence including post translational modifications (PTMs). It is a recombinant humanized IgG1k antibody with any process-related impurities removed through various purification steps. The heavy chain of this mAb is known to have a high abundance of PTMs such as N-terminal pyroglutamination, c-terminal lysine clipping, and glycosylation. 10µg/µL of raw sample was diluted with deionized water to 0.5µg/µL prior to injection. No desalting procedure is necessary for this series of CEMS experiments. The ZipChip HR chip was primed with background electrolyte solution (BGE) consisting of 0.2% acetic acid and 10% IPA (pH=3.17). Once a stable electrospray was observed, 10μ L of 0.5μ g/ μ L mAb was pipetted into the sample reservoir. Pressure injection with 2 psi for 4s was used for sample loading, introducing 0.4nL corresponding to 0.2ng of mAb into the separation channel. 20kV was applied for CE separation within 22 cm-length of channel, and ~2kV was used for nano-ESI. Each run was finished in less than 3 minutes. The NIST mAb standard was labeled using click chemistry with a negatively charged fluoresceine derivative or biotin, which were attached on both N-linked glyco units on the heavy chain, adding either two times1145.37Da for AF488 or two times 857.03Da for the biotin label to the MW of the antibody. The Q Exactive HF was set to the optimized conditions for ultra-high mass biomolecule, and to maintain a scan rate of 6 scans/sec. Insource CID (100V) was applied to assist desolvation. m/z range (2500~6000) was selected for this mildly denaturing condition. BioPharma Finder 2.0 was used throughout for data analysis. The sequence and PTM information of the NIST mAb was first set up in protein sequence manager. The identification of different variants can be accomplished after the mass spectra were deconvoluted to the intact mass with the ReSpect algorithm.

Workflow

Figure 1. Characterization of mAb/ADC is accomplished by separation with the ZipChip device, on-line analysis with high resolution Q Exactive Plus or Q Exactive HF with BioPharma mass spectrometer, and identification with **BioPharma Finder 2.0 software.**

generated, using AF488, Biotin and dylight800. CEMS analysis in Figure 8

Figure 5. A) Electropherogram of the NIST mAb in a 3 min run on a HR microfluidic chip hyphenated to Q Exactive HF BioPharma mass spectrometer. Three different lysine variants were separated. B) Three mass spectra were extracted from the three peaks of the electropherogram. Lysine variant (128Da) can be identified after the comparison of deconvoluted mass spectra. Higher number of lysine on the C-terminal of heavy chain provides higher mobility due to the additional positive charges from lysine

CONCLUSIONS

- NISTmAb and NISTmAb derived ADC samples with charge variants were separated and characterized using microfabricated glass chips in a CEMS experiment in less than 3 minutes by coupling the 908 ZipChip to a Q Exactive HF MS with Biopharma option. No sample preparation and desalting was necessary.
- Most proteoforms listed in the NIST mAb Reference Material were identified via CEMS: 5 glycosylated variants including GOF/GOF, GOF/G1F, G1F/G1F, G1F/G2F, and G2F/G2F from 2-lys, 1-lys, and 0-lys migration time frames.
- The relative sample amounts of the detected charge variants covers 3 orders of dynamic range.
- Despite the acidic separation conditions, charge state envelope of 26-31 is very close to native conditions for the mAb.

• The NISTmAb derived ADCs exhibit, as expected, the same charge heterogeneity.

• For the AF488 and Biotin as payloads, only the variant with 2 payloads were observed confirming the high yield of the click chemistry.
