ABSTRACT

Pesticides are widely used in food production and to control and manage various unwanted species. The detection, quantification, and confirmation of pesticide residue in food at trace levels requires sensitive, selective and robust analytical instrumentation. With ever increasing pressure to analyze contaminants at very low levels in a greater number of sample and with shorter turnaround times, laboratories seek continuous improvements in analytical instrumentation in order to maximize productivity and reduce downtime.

This study describes an optimized sample extraction and the analysis of multi-residue pesticides in baby food using femtogram-level sensitivity on a Thermo Scientific™ GC-MS/MS system. Sensitive detection and quantification of pesticides in baby foods is of particular importance as infants are more vulnerable to adverse health effects from these chemicals than adults.

In this work, commercially available fruit and vegetable based baby-food samples were subjected to an optimized Quick, Easy, Cheap, Effective, Rugged, and Safe (QuEChERS) extraction method to isolate the pesticide residues using acetonitrile as the final extraction solvent. Direct analysis of extracts in acetonitrile is desired to avoid the need for solvent exchange to a more GC amenable solvent. The QuEChERS extracts were then analyzed for pesticide residue content using a fast, targeted, time-SRM method for >200 pesticides (inclusive of priority pesticides). The performance of the method focused on assessing various quantitative parameters for analysis of over 200 pesticides. The results show outstanding limit of detection (LOD) (as low as 0.005 µg/kg), robustness (over 900 matrix injections with no maintenance) and linear responses over up to 5 orders of magnitude (0.025 – 250 µg/kg) for the compounds investigated. The data presented in this study demonstrates unprecedented method performance from sample preparation to sensitive and robust GC-MS/MS analysis in addition to automated data processing and reporting capabilities.

INTRODUCTION

The detection and subsequent quantification of pesticide residues and other chemical residues and contaminants is of paramount importance, especially when the food stuff is intended to be consumed by infants or young children.

In the European Union (EU), the maximum residue level (MRL) for the majority of pesticide-commodity combinations is set at the default level of 10 µg/kg.¹⁻³ However, a small number of pesticides and their metabolites may allow infants and young children (under worst-case intake conditions) to exceed the acceptable daily intake (ADI) values. The EU has therefore established MRLs, between 3-8 µg/kg for a number of specific pesticides prohibited in baby foods.⁴ The use of GC-MS/MS for the detection and identification of residues of prohibited compounds, in compliance with the residue definitions, have proved challenging, especially when the diverse composition of multi-ingredient baby foods are taken into account. Also, the increased levels of selectivity and sensitivity provided by triple quadrupole instruments compared to single quadrupole instruments enabled analysts to adopt faster, less specific sample extraction procedures. The QuEChERS procedure has become the standard approach for sample preparation in many laboratories because of an improvement in productivity.⁵

In this study, the quantitative performance of the Thermo Scientific™ TSQ™ 9000 triple quadrupole GC-MS/MS system with AEI source was assessed for the analysis of >200 pesticides in baby food at very low concentrations (as low as 0.025 µg/kg). A complete evaluation of method performance include: Sample preparation, overall method suitability measured from pesticides recoveries, selectivity, sensitivity, linearity and long term robustness.

MATERIALS AND METHODS

To test the linearity and dynamic range of the system, post-spiked carrot/potato and apple/pear baby food samples were prepared using the citrate buffered QuEChERS protocol using Thermo Scientific™ HyperSep™ dispersive solid phase extraction (dSPE) products. Immediately after dSPE clean up the final extracts (1 g sample/mL of acetonitrile) were acidified with 5% formic acid in acetonitrile and were spiked with a mixture of 211 pesticides (including internal standard) at 14 concentrations spanning a range of 0.025–250 µg/kg. Robustness was tested using repeat injections of samples (carrot/potato) spiked at the 10 µg/kg level. For method evaluation, pre-spiked carrot/potato and apple/pear/banana baby food sample extracts were each prepared at 1.0, 2.5 and 10.0 µg/kg (n = 6 for each concentration). Instrument conditions are shown in table 1.

Tuning parameters:	AEI SmartTune - 50eV			
Collision gas and pressure:	Argon at 70 psi			
Peak Width:	0.7 Da (both Q1 and Q3 @FWHM)			

RESULTS

The experiments described here evaluate the sample preparation procedure and the quantitative performance of the TSQ 9000 GC-MS/MS system with Advanced Electron Ion (AEI) source for the analysis of pesticides in baby food matrices. Pesticide recoveries were obtained from the extracts performed on the samples spiked before extraction. All detected compounds, at the three spiking levels in both matrices satisfied all SANTE requirements.³ More than 98% of the target pesticide residues had recoveries between 70 – 120% and at the 10 µg/kg spiking level with only one pesticide displaying a precision >20% (anthraquinone in carrot/potato). An example of the recovery and precision data is displayed in Figure 1.

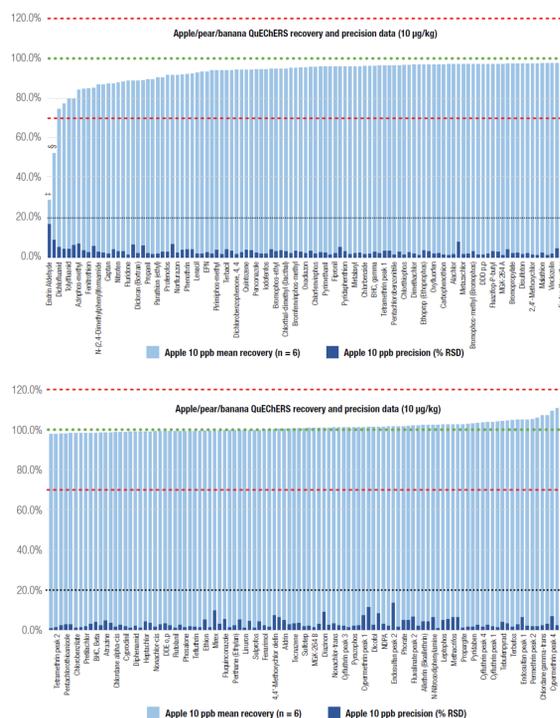

Figure 1. Recovery and precision data for apple/pear/banana extractions (n=6) at a concentration of 10 µg/kg.

Compound linearity was assessed by injecting matrix matched standards in the range of 0.025 to 250 µg/kg in duplicate for both carrot/potato and apple/pear/banana. Both sets of linearity data showed $R^2 > 0.990$ and RRF % RSDs of <20% for over 96% of component peaks indicating excellent linear response.

Figure 2 shows the lowest detectable standard for dichlorobenzil, dieldrin and deltamethrin which satisfies SANTE requirements. The MRLs are 10 µg/kg, 3 µg/kg* and 10 µg/kg respectively. Calibration curves show duplicate injection at 14 discrete levels ranging from 0.025 to 250 µg on column. *Dieldrin is classed as a prohibited pesticide and 3 µg/kg is considered to be the current limit of quantification, but is subject to regular review.⁴

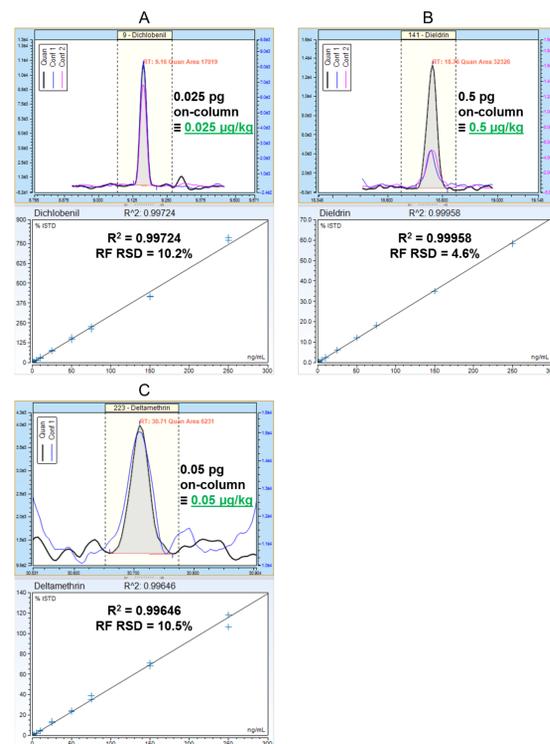

Figure 2. Example (A - dichlorobenzil, B - dieldrin and C - deltamethrin) chromatographic peaks showing the lowest detectable matrix matched carrot/potato standard which meets SANTE requirements.

System sensitivity, defined as instrumental detection limits (IDLs) was determined experimentally by performing n=10 replicates of the lowest matrix matched standard of carrot and potato that met all SANTE criteria. Calculations of IDLs were then made using one-tailed student t-test at the 99% confidence interval for the corresponding degrees of freedom and taking into account the concentration and absolute peak area %RSD for each compound (Figures 3 and 4).

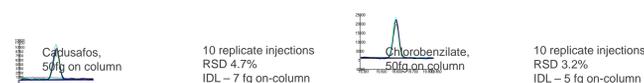

Figure 3. Example quantification SRM overlays of cadusafos and chlorobenzilate injected at the lowest level that met all SANTE criteria. Annotated are on column concentration, % RSD derived from absolute peak area response and calculated IDLs.

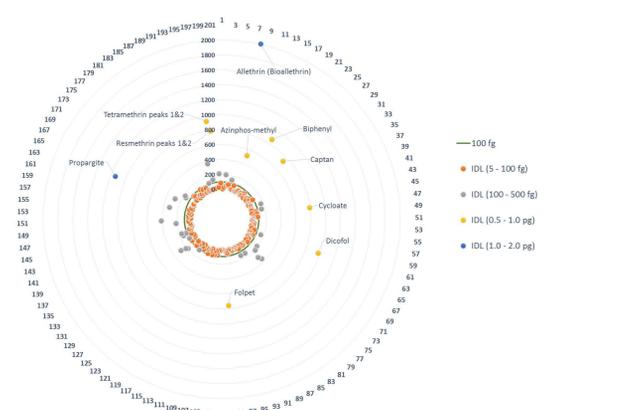

Figure 4. Plot showing the calculated IDLs for all pesticides. IDLs ranged from ~5 fg (chlorobenzilate) to ~2.0 pg (bioallethrin) with >95% of compounds showing an IDL of less than 500 fg on column (equivalent to 0.5 µg/kg in sample extract – carrot/potato).

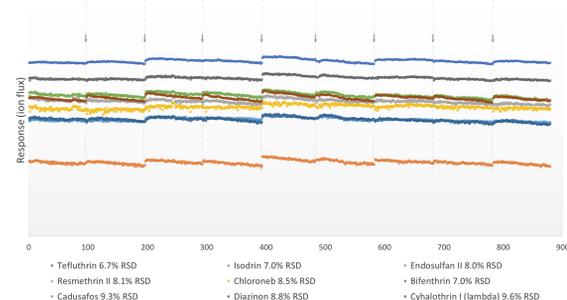

Figure 5. Robustness data showing almost 900 sequential injections of carrot/potato matrix sample extract spiked at 10 ppb. Injector maintenance and tuning intervals are marked with an arrow. No source cleaning was performed during the sequence.

The TSQ 9000 GC-MS/MS system with the AEI source was set-up as described in Table 1. After an initial source cleaning, repeat injections of a sample extract (1g/mL carrot and potato) spiked at the default MRL (10 µg/kg) were made. Extracts resulting from the QuEChERS methodology contain a lot of undesirable matrix co-extracted components which can easily contaminate the GC inlet, the chromatographic column and the MS ion source. In order to test the robustness of the AEI source only, after every ~100 sample injections, the PTV liner was replaced along with the injector septum, approximately 10 cm trimmed from the guard column followed by automatic tuning of the system using the Thermo Scientific™ SmartTune feature. SmartTune uses the MS parameters established during the initial tuning on a clean source and intelligently assess the performance of the system, only re-tuning when MS performance has been compromised. No additional maintenance was performed.

CONCLUSIONS

In this work it has been demonstrated that by using QuEChERS with Thermo Scientific HyperSep dispersive solid phase extraction (dSPE) and a direct injection of acetonitrile extracts, the TSQ 9000 GC-MS/MS system with the AEI source delivers outstanding quantitative performance for low level pesticide residue analysis in baby food.

- Direct analysis of acetonitrile extracts using an optimized PTV injection.
- QuEChERS extraction and subsequent clean-up of over 200 pesticides from replicate analysis (n=6 each at three concentrations) of each of two sample matrices, demonstrating excellent accuracy (recovery) and precision.
- Accurate, quantitative analysis of over 200 pesticides over up to 5 orders of magnitude (0.025 – 250 µg/kg), showing outstanding LODs and linear responses.
- Source robustness displayed over ~900 consecutive injections of sample matrix (1 g/mL).
- High sensitivity providing the real possibility to dilute the sample extract, thus limiting matrix contamination and system maintenance, leading to a potential increase in laboratory productivity.
