Dynabeads™ M-280 Streptavidin contains 10 mg (~6–7 × 10⁹) of magnetic beads/mL in phosphate buffered saline (PBS) pH 7.4, with 0.1% bovine serum albumin (BSA) and 0.02% sodium azide as preservatives.

Required materials

- DynaMag™ Magnet (See thermofisher.com/magnets for recommendations on magnets appropriate for manual or automated protocols)
- Mixing device with tilting and rotation (e.g. HulaMixer™ Sample Mixer)
- Buffers and Solutions (see Table 1)
- For biotinylation details, download the Molecular Probes Handbook from thermofisher.com/handbook

Product description

Dynabeads™ M-280 Streptavidin are ideal for numerous applications, including purification of proteins and nucleic acids, protein interaction studies, immunoprecipitation, immunoassays, phage display, biopanning, drug screening and cell isolation.

Add the beads to a sample containing biotinylated molecules, e.g. peptides, proteins, antibodies, sugars, lectins, oligonucleotides, DNA/RNA. During a short incubation, the biotinylated molecule will bind to the beads. Separate the molecule-bead capture, washing, and detection can be optimized for manual or automated use. With indirect capture, mix the biotinylated molecule with the sample to capture the molecule-target complex before adding the beads. Indirect target capture is an advantage when molecule-target kinetics are slow, affinity is weak, molecule concentration is low, or molecule-target binding requires optimal molecule orientation and true liquid-phase kinetics.

General guidelines

- Keep the tube on the magnet for 2 min to ensure that all the beads are collected on the tube wall.
- For diluted samples, increase the incubation time or isolate in smaller batches using the same beads in each batch.
- Avoid air bubbles during pipetting.
- Free biotin in the sample will reduce the binding capacity of the beads. A disposable separation column or a spin column will remove unincorporated biotin.
- For some applications it can be an advantage to add a detergent such as 0.01–0.1% Tween™ 20 to the washing/binding buffers to reduce non-specific binding.
- Run the PCR with limiting concentrations of biotinylated primer, or remove free biotinylated primer by ultrafiltration, microdialysis or other clean-up protocols (PCR clean-up products are available from thermofisher.com).

Required materials for coupling of proteins:

- 2 mL binding/mg
- 10 mL binding/mg

* Oligonucleotides and DNA fragments
For oligonucleotides, capacity is inversely related to molecule size (number of bases). Reduced binding capacity for large DNA fragments may be due to steric hindrance.

Protocol

Recommended washing buffers

- Nucleic acid applications: 1X B&W Buffer (see Table 1 for recipe). Dilute to 1X B&W Buffer with distilled water.
- Antibody/protein applications: PBS, pH 7.4.

Wash Dynabeads™ magnetic beads

Calculate the amount of beads required based on their binding capacity (see Table 2), and transfer the beads to a new tube.

1. Resuspend the beads in the vial (i.e. vortex for >30 sec, or tilt and rotate for 5 min).
2. Transfer the desired volume of beads to a tube.
3. Add an equal volume of Washing buffer, or at least 1 mL, and mix (vortex for 5 sec, or keep on a roller for at least 5 min).
4. Place the tube on a magnet for 1 min and discard the supernatant.
5. Remove the tube from the magnet and resuspend the washed beads in the same volume of washing buffer as the initial volume of beads taken from the vial (step 2).

The salt concentration and pH (typically 5–9) of the chosen binding/washing buffers can be varied depending on the type of molecule to be immobilized. Beads with immobilized molecules are stable in common buffers.

Both the size of the molecule to be immobilized and the biotinylation procedure will affect the binding capacity. The capacity for biotinylated molecules depends on steric availability and charge interaction between bead and molecule and between molecules. There are two or three biotin binding sites available for each streptavidin molecule on the surface of the bead after immobilization.

- Optimize the quantity of beads used for each individual application by titration.
- Use up to two-fold excess of the binding capacity of the biotinylated molecule to saturate streptavidin.
- Binding efficiency can be determined by comparing molecule concentration before and after coupling.

Table 2: Typical binding capacities for one mg of Dynabeads™ magnetic beads.

For research use only. Not for use in diagnostic procedures.
Dynabeads™ magnetic beads for RNA manipulation

As Dynabeads™ Streptavidin are not supplied in RNase-free solutions, perform the following steps after washing for RNA applications:

1. Wash the beads twice in Solution A for 2 min. Use the same volume (or larger) of Solution A as the initial volume of beads taken from the vial.
2. Wash the beads once in Solution B. Use the same volume of beads as in step 5.
3. Resuspend the beads in Solution B.

The beads are now ready to be coated with the biotinylated molecule of your choice.

Immobilization protocol

Wash the Dynabeads™ magnetic beads according to “Wash Dynabeads™ magnetic beads” section before use.

1. Add the biotinylated molecule to the washed beads.
2. Incubate for 15–30 min at room temperature with gentle rotation of the tube.
3. Place the tube in a magnet for 2–3 min and discard the supernatant.
4. Wash the coated beads 3–4 times in washing buffer.
5. Resuspend to desired concentration in a suitable buffer for your downstream use.

Here are some examples of immobilization protocols for specific applications.

Immobilize nucleic acids

1. Resuspend beads in 2X B&W Buffer to a final concentration of 5 µg/µL (twice original volume).
2. To immobilize, add an equal volume of the biotinylated DNA/RNA in distilled water to dilute the NaCl concentration in the 2 B&W Buffer from 2 M to 1 M for optimal binding.
3. Incubate for 15 min at room temperature using gentle rotation. Incubation time depends on the nucleic acid length: short oligonucleotides (<30 bases) require max. 10 min. DNA fragments up to 1 kb require 15 min.
4. Separate the biotinylated DNA/RNA coated beads with a magnet for 2–3 min.
5. Wash 2–3 times with a 1X B&W Buffer.
6. Resuspend to the desired concentration. Binding is now complete. Resuspend the beads with the immobilized DNA/RNA fragment in a buffer with low salt concentration, suitable for downstream applications.

Immobilize antibodies/proteins

1. Incubate the beads and biotinylated antibodies in PBS for 30 min at room temperature using gentle rotation.
2. Separate the antibody-coated beads with a magnet for 2–3 min.
3. Wash the coated beads 4–5 times in PBS containing 0.1% BSA.
4. Resuspend to the desired concentration for your application.

Automation

Magnetic separation and handling using Dynabeads™ magnetic beads can easily be automated on a wide variety of liquid handling platforms. Dynabeads™ MyOne™ Streptavidin T1 share similar properties to Dynabeads™ M-280 Streptavidin but are smaller, making them ideal for automation applications due to their small size, low sedimentation rate and high magnetic mobility. Selected protocols are available at thermofisher.com/automation.

Description of materials

Dynabeads™ Streptavidin are uniform, superparamagnetic beads of 2.8 µm in diameter with a streptavidin monolayer covalently coupled to the surface. This layer ensures negligible streptavidin leakage while the lack of excess adsorbed streptavidin ensures batch consistency and reproducibility of results.
