EZ-Link NHS-PEG₁₂-Biotin

<u>21312</u>	Rev. A.0 Pub. Part No. 2161895.5
Number	Description
21312	EZ-Link NHS-PEG ₁₂ -Biotin, 25mg
21313	EZ-Link NHS-PEG ₁₂ -Biotin, 500mg
	Form: Waxy solid Molecular Weight: 941.09 Spacer Arm: 56Å Net Mass Addition: 825.64
	$\begin{array}{c c} & 56 \text{ \AA} & & & & \\ & & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & $

Storage: Upon receipt store desiccated at -20°C protected. Product is shipped at ambient temperature.

Introduction

Thermo ScientificTM EZ-LinkTM NHS-PEG₁₂-Biotin reagent enables simple and efficient biotin labeling of antibodies, proteins and any other primary amine-containing macromolecule. The hydrophilic polyethylene glycol (PEG) spacer arm imparts water solubility that is transferred to the biotinylated molecule. For example, antibodies labeled with NHS-PEG₄-Biotin exhibit less aggregation when stored in solution as compared to antibodies labeled with reagents having only hydrocarbon spacers. Specific labeling of cell surface proteins is another useful application for these water-soluble and membrane-impermeable reagents.

Biotin is a small, naturally occurring vitamin that binds with high affinity to avidin and streptavidin proteins. Biotinylated proteins typically retain biological activity because the biotin group is relatively small. An antibody conjugated with several biotin molecules can amplify signal, thereby increasing the sensitivity of many assays. The bond formation between biotin and avidin is rapid and, once formed, is unaffected by most extremes of pH, organic solvents and other denaturing agents. Labeled proteins can be purified using immobilized streptavidin, avidin or Thermo ScientificTM NeutrAvidinTM Protein affinity resins and detected in ELISA, dot blot or Western blot applications.

N-Hydroxysuccinimide (NHS) esters are the most commonly used biotinylation reagents. In pH 7-9 buffers, NHS-biotin reagents react efficiently with primary amino groups (-NH₂) by nucleophilic attack, forming an amide bond and releasing the NHS. Proteins typically have many sites for labeling, including the primary amine in the side chain of lysine (K) residues and the N-terminus of each polypeptide.

Cell surface biotinylation has emerged as an important tool for studying the expression and regulation of receptors and transporters, differentiation of plasma membrane proteins from those localized to organelle membranes, and distribution of membrane proteins in polarized epithelial cells. Because EZ-Link NHS-PEG₁₂-Biotin dissolves readily in polar solutions, it does not permeate the cell membrane. As long as the cell remains intact, only primary amines exposed on the surface will be biotinylated with this reagent.

Important Product Information

- The EZ-Link NHS-PEG₁₂-Biotin is a viscous liquid or waxy solid that is difficult to weigh and dispense. To facilitate handling, make a stock solution immediately before first use by dissolving the reagent in dry (anhydrous, molecular-sieve treated) organic solvent, such as dimethylformamide (DMF, Product No. 20673) and dimethylsulfoxide (DMSO, Product No. 20688). Minimize reagent exposure to moisture because the NHS-ester reactive group is susceptible to hydrolysis. Store unused stock solution in a moisture-free condition (e.g., capped under an inert gas such as argon or nitrogen) at -20°C. Equilibrate reagent vial to room temperature before opening to avoid moisture condensation inside the container. Minimize exposure to air by keeping the stock solution capped by a septum through which reagent can be removed with a syringe. With proper handling, the stock solution is stable for three months.
- Avoid buffers containing primary amines (e.g., Tris or glycine) during conjugation because they compete with the intended reaction. If necessary, dialyze or desalt samples into a buffer such as phosphate-buffered saline (PBS).
- The reagent-to-protein molar ratio affects modification extent of available amine groups. Optimize this ratio to yield the extent of biotinylation that is best for the specific application.

Additional Materials Required

- Water-miscible organic solvent (molecular sieve-treated) such as dimethylsulfoxide (DMSO, Product No. 20688) or dimethylformamide (DMF, Product No. 20673) for preparing reagent stock solution
- Small-volume, non-coring needle for dispensing reagent stock solution while minimizing exposure to the air
- Phosphate-buffered saline (PBS) or other amine-free buffer at pH 7-8 for use as reaction buffer (see Important Product Information and Related Thermo Scientific Products)
- Desalting columns or dialysis units for buffer exchange and removal of excess reagent following modification (e.g., Thermo Scientific Zeba Spin Desalting Columns or Slide-A-Lyzer Dialysis Units)

Procedure for Protein Biotinylation using EZ-Link NHS-PEG₁₂-Biotin

The amount of reagent to use for a reaction depends on the amount of labeling desired, the amount of protein to be labeled, and its concentration. By regulating the molar ratio of reagent to target molecule, the extent of labeling can be controlled. As a starting point, consider using a 5- to 20-fold molar excess of EZ-Link NHS-PEG₁₂-Biotin for protein solutions > 2mg/mL. When labeling more dilute solutions, a greater relative molar excess of EZ-Link NHS-PEG₁₂-Biotin may be necessary to achieve the same labeling results. Example calculations for a typical antibody modification are provided for convenience.

A. Calculate the Amount of Reagent Needed

1. Calculate the quantity in millimoles of EZ-Link NHS-PEG₁₂-Biotin to add to the reaction for a 20-fold molar excess:

ml protein $\times \frac{\text{mg protein}}{\text{ml protein}} \times \frac{\text{mmol protein}}{\text{mg protein}} \times \frac{20 \text{ mmol Biotin Reagent}}{\text{mmol protein}} = \text{mmol Biotin Reagent}$

Note: the value 20 in this equation corresponds to the suggested reagent molar fold excess for a 2mg/mL protein sample.

2. Calculate microliters of 250mM NHS-PEG₁₂-Biotin stock solution (prepared in Step B.1) to add to the reaction:

mmol Biotin Reagent × $\frac{1,000,000 \,\mu l}{L}$ × $\frac{L}{250 \,\text{mmol}}$ = μl Biotin Reagent stock solution

Example Calculation:

For 1mL of a 2mg/mL IgG (150,000 MW) solution, ~1µL of 250mM NHS-PEG₁₂-Biotin reagent will be added:

$$1 \text{ ml IgG} \times \frac{2 \text{ mg IgG}}{1 \text{ ml IgG}} \times \frac{1 \text{ mmol IgG}}{150,000 \text{ mg IgG}} \times \frac{20 \text{ mmol Biotin Reagent}}{1 \text{ mmol IgG}} = 0.000266 \text{ mmol Biotin Reagent}$$

$$0.000266 \text{ mmol Biotin Reagent} \times \frac{1,000,000 \text{ µl}}{L} \times \frac{L}{250 \text{ mmol}} = 1.07 \text{ µl of } 250 \text{ mM Biotin Reagent stock solution}$$

B. Prepare 250mM Reagent Stock Solution

- 1. Read the Important Product Information (previous section) before preparing and storing this solution.
- 2. Remove vial of reagent from -20°C storage and fully equilibrate it to room temperature before opening.
- Prepare a 250mM Biotin Reagent Stock Solution by dissolving 25mg of EZ-Link NHS-PEG₁₂-Biotin (i.e., entire contents of Product No. 21312, approximately 25μL) in ~82μL of dry water-miscible solvent (e.g., DMF or DMSO). For Product No. 21313 (500mg), dissolve entire contents in ~1.63mL solvent to make a total volume of 2.13mL.
- 4. Cap, store and handle reagent stock solution as directed in the Important Product Information section.

C. Labeling Reaction

1. Dissolve 1-10mg protein to be modified in PBS according to the calculations made in section A.

Note: Protein that is already dissolved in amine-free buffer at pH 7.2-8.0 may be used without buffer exchange or dilution with PBS. Proteins in Tris or other amine-containing buffers must be exchanged into a suitable buffer.

- 2. Remove vial of Biotin Reagent Stock Solution from storage and fully equilibrate it to room temperature before use.
- 3. Using a syringe, remove an appropriate volume (see Calculations in section A) of 250mM Biotin Reagent Stock Solution, dispense it into the protein solution and mix well. If the required volume is too small to dispense accurately, remove a portion and prepare a diluted stock solution by adding additional dry solvent. Add the appropriate volume of diluted Reagent Stock Solution to the protein solution. Discard excess diluted reagent.
- 4. Incubate reaction on ice for two hours or at room temperature for 30 minutes.

Note: Other than the possibility of ordinary protein degradation or microbial growth, there is no harm in reacting longer than the specified time.

5. Labeling is complete at this point and, although excess nonreacted and hydrolyzed Biotin Reagent remains in the solution, it is often possible to perform preliminary tests of the labeled protein. Once proper function and labeling has been confirmed, the labeled protein may be purified from nonreacted Biotin Reagent using desalting or dialysis.

D. Determination of Biotin Incorporation (optional)

Biotin incorporation can be estimated using the HABA (4'-hydroxyazobenzene-2-carboxylic acid) method (e.g., Thermo Scientific Pierce Biotin Quantitation Kit, Product No. 28005). This method is based on the ability of the HABA dye to bind avidin, thereby forming a complex with maximal absorption at 500nm. Biotin is then added to the solution and, because of its higher affinity for avidin, biotin displaces the HABA and the absorption at 500nm decreases proportionately. The absorbance of the HABA-avidin solution is measured before and after adding the biotin-containing sample. The change in absorbance relates to the amount of biotin in the sample.

Example Procedure for Biotinylation of Cell Surface Proteins

Many variations of this procedure exist in the literature (see General References). Labeling may be performed on cells in suspension or on adherent cells in culture plates. In the latter situation, diffusion of the Biotin Reagent to all surfaces of the cells will be limited, and labeling will occur predominately on the exposed surface. Culture media must be washed from the cells; otherwise, amine-containing components will compete and quench the reaction to cell surface proteins. Using a more concentrated cell suspension is most effective because less biotin reagent is required in the reaction. Generally, a final concentration of 2-5mM Biotin Reagent is effective. NHS reactions occur more rapidly at higher pH; therefore, pH 8.0 is used in the following example so that labeling can be completed as quickly as possible.

- 1. Wash cells three times with ice-cold PBS (pH 8) to remove amine-containing culture media and proteins from the cells.
- 2. Suspend cells at a concentration of $\sim 25 \times 10^6$ cells/mL in PBS (pH 8).
- 3. Add 10-20µL of 250mM Biotin Reagent Stock Solution (prepared in above procedure, Section B) per mL of cell suspension (results in 2.5-5mM Biotin Reagent).
- 4. Incubate reaction mixture at room temperature for 30 minutes.

Note: Performing this incubation at 4°C may reduce active internalization of the Biotin Reagent.

- 5. Wash cells three times with PBS + 100mM glycine to quench and remove excess Biotin Reagent and byproducts.
- 6. Lyse and/or analyze biotin-labeled cells as required for the research method.

Troubleshooting

Problem	Possible Cause	Solution
Lack of biotinylation	No amines available on molecule of interest	Use a biotinylation reagent that targets a different functional group or convert sulfhydryl to amine using Thermo Scientific TM Aminoethyl-8 (Product No. 23010)
	Buffer contained primary amines	Use a non-amine containing buffer
		Extensively dialyze or desalt sample into a buffer free of primary amines
	Exposure of reagent to moisture caused hydrolysis of the NHS ester, inactivating the reagent	Ensure that reagent stock solution is not exposed to moisture
		Purchase new reagent
Biotinylated protein does not function in downstream application	Sites (primary amines) of biotinylation were active sites of molecule	Choose biotinylation reagent that targets different groups
	Excessive biotinylation	Reduce molar excess of biotinylation reagent, or reduce time or temperature for biotinylation
