**Introduction**

Molecular Probes offers Alexa Fluor® 488 dye–labeled colloidal gold conjugates. These conjugates consist of affinity-purified goat anti–mouse IgG or goat anti–rabbit IgG antibodies, or streptavidin, labeled with our Alexa Fluor 488 dye and adsorbed to 5 nm or 10 nm gold colloids (Table 1). The colloidal gold conjugates may be used as probes in immunoblotting, light microscopy, fluorescence microscopy or electron microscopy. Immunolabeled samples may also be further developed using silver-enhancement methods. As a separate product, we offer the LI Silver (LIS) Enhancement Kit (L-24919), which is prepared for Molecular Probes by Nanoprobes, Inc.

Combining fluorescent secondary detection reagents into colloidal gold to form functional complexes is difficult because the fluorescence of fluorophores, such as fluorescein, is significantly quenched by proximity to the colloidal gold.1 Molecular Probes makes fluorescent colloidal gold complexes with our Alexa Fluor 488 dye, a dye which has superior brightness and photostability. These Alexa Fluor 488 anti-IgG– or streptavidin–colloidal gold complexes may be used to perform correlated immunofluorescence and electron microscopy in a two-step labeling procedure, rather than in the three-step indirect labeling, required with conventional nonfluorescent anti-IgG– or streptavidin–colloidal gold complexes.2

**Materials**

**Contents**

The Alexa Fluor 488 dye–labeled colloidal gold conjugates are supplied in unit sizes of 0.5 mL as suspensions at ~30 µg of protein per mL in 10 mM Tris-HCl, pH 7.5, containing 0.1% BSA and 5 mM sodium azide.

**Storage**

Upon receipt, store the Alexa Fluor 488 dye–labeled colloidal gold conjugates at 2–6°C, undiluted and protected from light. DO NOT FREEZE. The products should be stable for at least 3 months.

**Application**

The Alexa Fluor 488 conjugates have a fluorescence excitation and emission maxima of approximately 495 nm and 519 nm, respectively. Because staining protocols vary with application, the appropriate dilution of the colloidal gold conjugates should be determined empirically. The supplied suspensions at ~30 µg/mL should be at a useful working concentration for most immunochemical applications.

It may be a good practice to centrifuge the protein conjugate solution before use in a microcentrifuge for 30 minutes and remove the supernatant. The soft pellet, containing the colloidal gold-adsorbed protein conjugate, is resuspended in buffer and added to the experiment. These steps will reduce the presence of fluorescently-labeled protein that may have dissociated from the colloid gold particles during storage. For some applications, the presence of the mixed conjugates may provide the additional fluorescence labeling, and therefore the product should simply be mixed well before use.
